Assessment of the efficacy of ofatumumab in patients with chronic lymphocytic leukaemia treated in the Department of Haematology and Bone Marrow Transplantation of the Medical University in Lublin – Preliminary results. *Ann Agric Environ Med*. doi: 10.5604/12321966.1233571

Abstract

Introduction. Despite significant recent advances in the treatment of chronic lymphocytic leukaemia (CLL), most cases of the disease are still incurable. Treatment with monoclonal antibodies, such as ofatumumab, is one of the new therapeutic options.

Objective. Retrospective analysis of the efficacy of ofatumumab in patients with chronic lymphocytic leukaemia (CLL) treated in the Haematology and Bone Marrow Transplantation Department of the Medical University of Lublin, Poland, during 2011–2013.

Materials and method. The analysis included 5 patients (3 women and 2 men), aged 47–65, with Rai stage II–IV CLL, after a few lines of treatment. Three patients received ofatumumab in monotherapy and 2 patients received ofatumumab in combination with cyclophosphamide (50 mg/day) and dexamethasone (40 mg/day). All patients included in the study were diagnosed with an active form of leukaemia with symptoms such as lymphocytosis or massive lymphadenopathy.

Results. All patients responded to the treatment. Within the first 8 weeks of the treatment, levels of white blood cells returned to normal in patients with baseline lymphocytosis (3 patients). An increase in platelet levels was reported in 3 patients. Haemoglobin levels were higher or comparable to the baseline values in all studied patients after the completion of immunotherapy. In the patient with massive lymphadenopathy and hepato- and splenomegaly, the size of the lymph nodes, spleen and liver decreased and neutrophil levels increased. Time of progression was 5–12 months, and in one patient partial remission has been maintained. The treatment was well-tolerated in most cases. Asymptomatic neutropenia and an infection with *Candida glabrata* were observed.

Conclusions. Ofatumumab may be a new and safe therapeutic option for patients with CLL after a few lines of treatment.

Key words

chronic lymphocytic leukemia, ofatumumab, monoclonal antibodies, immunotherapy

INTRODUCTION

Despite significant recent advances in the treatment of chronic lymphocytic leukaemia (CLL), such as the introduction of purine analogues and monoclonal antibodies, most cases of the disease are still incurable. Allogeneic transplantation of haematopoietic cells, which is an opportunity for a complete cure, can be used only in a small percentage of patients. For this reason, it is extremely important to use new drugs and therapeutic regimens which are available to a large number of patients with CLL, and which offer an opportunity for increased overall survival (OS). Currently, the FCR (Fludarabine, Cyclophosphamide, Rituximab) regimen is considered the gold standard in the first-line treatment of CLL in patients in overall good condition [1, 2]. Research

has shown that the introduction of FCR has beneficial effects on the number of complete remissions (CR) and overall survival (OS). Rituximab, the first widely-used anti-CD20 monoclonal antibody, is an important part of this regimen. Recently, new monoclonal antibodies, such as Camptah-1H (anti-CD52), ofatumumab and obinutuzumab (both directed against CD20), have been introduced. However, the treatment of patients with relapsed and refractory types of CLL is still a difficult and often unresolved clinical problem [1, 2, 3].

OBJECTIVE

The objective of this study is a retrospective analysis of the efficacy of ofatumumab in patients with chronic lymphocytic leukaemia (CLL) treated in the Haematology and Bone Marrow Transplantation Department of the Medical University in Lublin, Poland, during 2011–2013.

MATERIALS AND METHOD

The analysis included 5 patients diagnosed with chronic lymphocytic leukaemia during 1995–2007, Rai stage II–IV and after a few lines of treatment. The study group included 3 women and 2 men, all aged 47–65. Clinical characteristics are presented in Tables 1–3. They were all diagnosed with the active form of leukaemia that required treatment. Three patients (Nos. 1, 3 and 4) received ofatumumab due to lymphocytosis, whereas 2 other patients required treatment because of lymphadenopathy with hepatosplenomegaly (Nos.

Table 1. Clinical characteristics of patients treated with ofatumumab at the outset of therapy

	Gender	Age (years)	Rai clinical stage	Disease duration (months)	NO. of lines of treatment
Patient No. 1	M	65	III	196	9
Patient No. 2	F	47	III	122	7
Patient No. 3	F	51	II	66	3
Patient No. 4	F	57	IV	171	6
Patient No. 5	M	50	II	60	4

Patient No. 4	positive	positive	negative	negative
Patient No. 5	positive	positive	negative	negative

2 and 5). Before ofatumumab treatment, patients had been administered a few lines of chemotherapy. Fludarabine was a component of at least one of them.

In patients 1, 2 and 3, ofatumumab was used in monotherapy. The initial dose was 300 mg; subsequent doses were 2,000 mg. The regimen included 8 infusions administered every week for 8 consecutive weeks. After this time, ofatumumab was administered as a single dose of 2,000 mg/month. Patient No. 1 received 11, patient No 2–7 and patient No. 3–12 infusions of monoclonal antibody, according to the treatment regimen described above.

Patients 4 and 5 received ofatumumab in combination with cyclophosphamide (50 mg/day) and dexamethasone (40 mg/day) on days 1–4, 8–11, 15–18 and 22–25 of every 28-day treatment cycle. In this group of patients, ofatumumab was administered on days 1, 8, 15 and 22 of each 28-day (1,000mg/dose) treatment cycle. Both patients received 6 full cycles of the treatment.

All patients were administered premedication (paracetamol, clemastine and hydrocortisone or dexamethasone at a body mass-dependent dose) before the infusion of ofatumumab.

RESULTS

All patients responded to the treatment. Two patients, Nos. 1 and 5, achieved partial remission (PR) and 3 patients (Nos. 2, 3 and 4) reached stable disease (SD). Lymphocyte counts significantly decreased in patients with initial lymphocytosis (Nos. 1, 3 and 4) (Fig. 1; Tab. 4).

Figure 1. Lymphocyte counts in patients 1, 3 and 4, before, during and after ofatumumab treatment

Figure 2. A: Lymph nodes of the patient no 5 before ofatumumab treatment. B: Lymph nodes of the same patient after ofatumumab treatment

Table 4. Haemoglobin, lymphocyte and platelet counts in the studied group before and after ofatumumab treatment.

	Patient No. 1	Patient No. 2	Patient No. 3	Patient No. 4	Patient No. 5
Haemoglobin levels before the treatment	10.7 g/dl	10.0 g/dl	11.6 g/dl	11.7 g/dl	15.4 g/dl
Haemoglobin levels after the treatment	13.4 g/dl	12.2 g/dl	14.9 g/dl	11.7 g/dl	16.1 g/dl
Lymphocyte counts before the treatment	259.0 K/ μ l	4.89 K/ μ l	153.4 K/ μ l	45.06 K/ μ l	1.14 K/ μ l
Lymphocyte counts after the treatment	3.13 K/ μ l	3.42 K/ μ l	11.22 K/ μ l	3.95 K/ μ l	5.85 K/ μ l
Platelet counts before the treatment	126.0 K/ μ l	111.0 K/ μ l	177.0 K/ μ l	60.0 K/ μ l	103.0 K/ μ l
Platelet counts after the treatment	137.0 K/ μ l	83.0 K/ μ l	163.0 K/ μ l	102.0 K/ μ l	189.0 K/ μ l

Platelet counts increased in patients 4 and 5 in comparison to the baseline values. Haemoglobin levels were higher or comparable to the baseline values in all studied patients after the completion of immunotherapy (Tab. 4).

In patient No. 5, who was treated with immunotherapy because of massive lymphadenopathy (Fig. 2A) and hepatosplenomegaly, the size of the lymph nodes (Fig. 2B), spleen and liver significantly decreased.

The clinical stage of the disease was reduced in 3 patients: patient No. 1 (initially – Rai stage III, stage II – after the treatment), patient No. 4 (initially – Rai stage IV, stage III – after the treatment), patient No. 6 (initially – Rai stage II, stage I – after the treatment).

Progression-free survival, defined as the time from the initiation of ofatumumab treatment to the progression of the disease or death of a patient, was 5–12 months. In one case, partial remission has been maintained until the date of publication (Tab. 5). Overall survival (OS), understood as the time from the initiation of immunotherapy to the death of a patient, was determined for only one patient (No. 1), who

	Patient No.1**	Patient No.2**	Patient No.3**	Patient No.4**	Patient No.5***
PFS (months)	9	9	5	12	-
OS (months)	24	-	-	-	-

* patients with partial remission, with no signs of progression

** living patients

died because of the progression of leukaemia. Other patients are still being followed-up (Tab. 5).

The treatment was well-tolerated in most cases. Asymptomatic neutropenia (grade 2) and transient elevation in transaminases (Alat – grade 3) were observed in patient No 5. Administration of growth factors and hepatoprotective agents resulted in normalization of these parameters. Despite premedication, patient No 4 had infusion reactions (skin redness and rash) after every administration of ofatumumab. He required continuous use of anti-histamines. Moreover, asymptomatic infection with *Candida glabrata* was observed during the sixth cycle of the treatment.

DISCUSSION

Precise identification of genetic and immunological profile of patients with chronic lymphocytic leukaemia, and thus the assessment of risk factors, helps to customize the treatment. At the same time, despite significant advances in the therapy of chronic lymphocytic leukaemia (CLL), most cases of the disease are still incurable. The combination of monoclonal antibodies with chemotherapy (FCR regimen) leads to a large number of complete remissions and higher overall survival rates in many patients. However, patients refractory to purine analogues, especially fludarabine, who constitute a group with an extremely unfavourable prognosis, are still an important and unresolved problem [4].

Available therapeutic option are usually limited due to the advanced age of patients, concomitant diseases and prior cytostatic treatment. One of the retrospective, single-centre studies proved low efficacy of various, also aggressive, treatment options. The response rate was only 23%, while the risk of infectious complications was high for 54% of the patients. Monotherapy with rituximab was one of the available options, but it proved to be disappointing due to the lack of response and median OS of only 6 months [5].

Attempts to solve this difficult issue included the treatment with ofatumumab, a new anti-CD-20 monoclonal antibody. It is believed that this antibody is more active than rituximab because it binds to a different epitope which includes both the large and small extracellular domains of CD20, and it has slower dissociation rate [6, 7].

In 2009, 2 clinical trials were especially important for the FDA approval of ofatumumab in the therapy of previously treated CLL patients. In one of the studies, Coiffier et al. treated 33 patients with refractory/relapsed CLL with ofatumumab in monotherapy and obtained a partial response (PR) in 48% of patients. Median progression-free survival was just over 3 months (106 days) [8]. The other study included patients with relapsed CLL who had been treated previously with fludarabine and alemtuzumab, and those with bulky lymphadenopathy. The response rate was 58 and 47% (complete remission was achieved in one case) and PFS was 5.7 and 5.9 months, respectively [9].

These results, favourable in terms of the efficacy of ofatumumab in the monotherapy of patients with CLL and poor prognosis, were not replicated by Moreno et al. The response rate in this case was only 22%, PFS was 5 months and OS – 11 months [10].

Although the group of patients presented in this paper was small, it is worth noting that all of them responded to the treatment with ofatumumab. The best result (PR) was achieved in patient No. 1, whose morphological parameters significantly improved, despite the advanced stage and long-term course of the disease and the largest number of prior therapies. In patient No. 5, a spectacular improvement of lymphadenopathy was observed, which proves the efficacy of ofatumumab in patients with bulky CLL, which had been reported previously by Wierda et al. [11]. In this case, ofatumumab was combined with cyclophosphamide and dexamethasone, which probably had a positive effect on the treatment results. Synergistic action of ofatumumab and dexamethasone with high response rates and good tolerability were also reported by Castro et al and Doubek et al. [12]. Attempts are now being made to combine ofatumumab with other drugs, such as bendamustine [13] or lenalidomide [14].

The treatment was well-tolerated by the patients presented in this paper. There was only one asymptomatic granulocytopenia (grade 2), transient elevation in transaminases (grade 3) and asymptomatic infection with *Candida glabrata*. One patient had an infusion reaction (skin redness and rash).

Cytometric analyses have shown that ofatumumab probably plays a role in the rapid and prolonged depletion of circulating normal B lymphocytes, which may lead to cytopenia and infectious complications [8]. Safety and good tolerability of ofatumumab have also been confirmed in studies by other authors [8, 9]. Interestingly, Österborg et al. have proved the high efficacy of ofatumumab retreatment in patients who initially responded to the therapy and then relapsed.

CONCLUSIONS

Ofatumumab may be a new and safe therapeutic option for patients with poor prognosis after a few lines of the treatment. Beneficial effects of ofatumumab may be increased by its combination with other drugs, such as dexamethasone and cyclophosphamide. Further research is needed to confirm these hypotheses.
